

## 16 Global Mincut

Given an **undirected, capacitated graph**  $G = (V, E, c)$  find a partition of  $V$  into two non-empty sets  $S, V \setminus S$  s.t. the capacity of edges between both sets is minimized.

## 16 Global Mincut

We can solve this problem using standard maxflow/mincut.

- ▶ Construct a directed graph  $G' = (V, E')$  that has edges  $(u, v)$  and  $(v, u)$  for every edge  $\{u, v\} \in E$ .
- ▶ Fix an arbitrary node  $s \in V$  as source. Compute a minimum  $s$ - $t$  cut for all possible choices  $t \in V, t \neq s$ . (Time:  $\mathcal{O}(n^4)$ )
- ▶ Let  $(S, V \setminus S)$  be a minimum global mincut. The above algorithm will output a cut of capacity  $\text{cap}(S, V \setminus S)$  whenever  $|\{s, t\} \cap S| = 1$ .

# Edge Contractions

- ▶ Given a graph  $G = (V, E)$  and an edge  $e = \{u, v\}$ .
- ▶ The graph  $G/e$  is obtained by “identifying”  $u$  and  $v$  to form a new node.
- ▶ Resulting parallel edges are replaced by a single edge, whose capacity equals the sum of capacities of the parallel edges.

## Example 88

- ▶ Edge-contractions do not decrease the size of the mincut.

# Edge Contractions

We can perform an edge-contraction in time  $\mathcal{O}(n)$ .

# Randomized Mincut Algorithm

**Algorithm 52** KargerMincut( $G = (V, E, c)$ )

- 1: **for**  $i = 1 \rightarrow n - 2$  **do**
- 2:     choose  $e \in E$  randomly with probability  $c(e)/C(E)$
- 3:      $G \leftarrow G/e$
- 4: **return** only cut in  $G$

- ▶ Let  $G_t$  denote the graph after the  $(n - t)$ -th iteration, when  $t$  nodes are left.
- ▶ Note that the final graph  $G_2$  only contains a single edge.
- ▶ The cut in  $G_2$  corresponds to a cut in the original graph  $G$  with the same capacity.
- ▶ What is the probability that this algorithm returns a mincut?

# Example: Randomized Mincut Algorithm

**What is the probability that this algorithm returns a mincut?**

**What is the probability that a given mincut  $A$  is still possible after round  $i$ ?**

- ▶ It is still possible to obtain cut  $A$  in the end if so far **no** edge in  $(A, V \setminus A)$  has been contracted.

# Analysis

What is the probability that we select an edge from  $A$  in iteration  $i$ ?

- ▶ Let  $\min = \text{cap}(A, V \setminus A)$  denote the capacity of a mincut.
- ▶ Let  $\text{cap}(v)$  be capacity of edges incident to vertex  $v \in V_{n-i+1}$ .
- ▶ Clearly,  $\text{cap}(v) \geq \min$ .
- ▶ Summing  $\text{cap}(v)$  over all edges gives

$$2c(E) = 2 \sum_{e \in E} c(e) = \sum_{v \in V} \text{cap}(v) \geq (n - i + 1) \cdot \min$$

- ▶ Hence, the probability of choosing an edge from the cut is at most  $\min / c(E) \leq 2 / (n - i + 1)$ .

$n - i + 1$  is the number of nodes in graph  $G_{n-i+1} = (V_{n-i+1}, E_{n-i+1})$ , the graph at the start of iteration  $i$ .

## Analysis

The probability that we do **not** choose an edge from the cut in iteration  $i$  is

$$1 - \frac{2}{n - i + 1} = \frac{n - i - 1}{n - i + 1} .$$

The probability that the cut is alive after iteration  $n - t$  (after which  $t$  nodes are left) is

$$\prod_{i=1}^{n-t} \frac{n - i - 1}{n - i + 1} = \frac{t(t - 1)}{n(n - 1)} .$$

Choosing  $t = 2$  gives that with probability  $1/\binom{n}{2}$  the algorithm computes a mincut.

# Analysis

Repeating the algorithm  $c \ln n \binom{n}{2}$  times gives that the probability that we are never successful is

$$\left(1 - \frac{1}{\binom{n}{2}}\right)^{\binom{n}{2} c \ln n} \leq \left(e^{-1/\binom{n}{2}}\right)^{\binom{n}{2} c \ln n} \leq n^{-c},$$

where we used  $1 - x \leq e^{-x}$ .

## Theorem 89

*The randomized mincut algorithm computes an optimal cut **with high probability**. The total running time is  $\mathcal{O}(n^4 \log n)$ .*

# Improved Algorithm

## Algorithm 53 RecursiveMincut( $G = (V, E, c)$ )

```
1: for  $i = 1 \rightarrow n - n/\sqrt{2}$  do
2:   choose  $e \in E$  randomly with probability  $c(e)/C(E)$ 
3:    $G \leftarrow G/e$ 
4: if  $|V| = 2$  return cut-value;
5:  $cuta \leftarrow$  RecursiveMincut( $G$ );
6:  $cutb \leftarrow$  RecursiveMincut( $G$ );
7: return  $\min\{cuta, cutb\}$ 
```

### Running time:

- ▶  $T(n) = 2T\left(\frac{n}{\sqrt{2}}\right) + \mathcal{O}(n^2)$
- ▶ This gives  $T(n) = \mathcal{O}(n^2 \log n)$ .

Note that the above implementation only works for very special values of  $n$ .

# Probability of Success

The probability of contracting an edge from the mincut during one iteration through the for-loop is only

$$\frac{t(t-1)}{n(n-1)} \approx \frac{t^2}{n^2} = \frac{1}{2},$$

as  $t = \frac{n}{\sqrt{2}}$ .

For the following analysis we ignore the slight error and assume that this probability is at most  $\frac{1}{2}$ .

# Probability of Success

We can estimate the success probability by using the following game on the recursion tree. Delete every edge with probability  $\frac{1}{2}$ . If in the end you have a path from the root to **at least one** leaf node you are successful.

# Probability of Success

Let for an edge  $e$  in the recursion tree,  $h(e)$  denote the height (distance to leaf level) of the parent-node of  $e$  (end-point that is higher up in the tree). Let  $h$  denote the height of the root node.

Call an edge  $e$  **alive** if there exists a path from the parent-node of  $e$  to a descendant leaf, after we randomly deleted edges. Note that an edge can only be alive if it hasn't been deleted.

## Lemma 90

*The probability that an edge  $e$  is alive is at least  $\frac{1}{h(e)+1}$ .*

# Probability of Success

## Proof.

- ▶ An edge  $e$  with  $h(e) = 1$  is alive if and only if it is not deleted. Hence, it is alive with probability at least  $\frac{1}{2}$ .
- ▶ Let  $p_d$  be the probability that an edge  $e$  with  $h(e) = d$  is alive. For  $d > 1$  this happens for edge  $e = \{c, p\}$  if it is not deleted **and** if one of the child-edges connecting to  $c$  is alive.
- ▶ This happens with probability

$$p_d = \frac{1}{2} (2p_{d-1} - p_{d-1}^2) \quad \boxed{\Pr[A \vee B] = \Pr[A] + \Pr[B] - \Pr[A \wedge B]}$$

$$= p_{d-1} - \frac{p_{d-1}^2}{2}$$

$$\geq \frac{1}{d} - \frac{1}{2d^2} \geq \frac{1}{d} - \frac{1}{d(d+1)} = \frac{1}{d+1} .$$

$x - x^2/2$  is monotonically increasing for  $x \in [0, 1]$

## 16 Global Mincut

### Lemma 91

*One run of the algorithm can be performed in time  $\mathcal{O}(n^2 \log n)$  and has a success probability of  $\Omega(\frac{1}{\log n})$ .*

*Doing  $\Theta(\log^2 n)$  runs gives that the algorithm succeeds with high probability. The total running time is  $\mathcal{O}(n^2 \log^3 n)$ .*
