

## Preflows

### Definition 1

An  $(s, t)$ -preflow is a function  $f: E \rightarrow \mathbb{R}^+$  that satisfies

1. For each edge  $e$

$$0 \leq f(e) \leq c(e).$$

(capacity constraints)

2. For each  $v \in V \setminus \{s, t\}$

$$\sum_{e \in \text{out}(v)} f(e) \leq \sum_{e \in \text{into}(v)} f(e).$$

## Preflows

### Example 2

A node that has  $\sum_{e \in \text{out}(v)} f(e) < \sum_{e \in \text{into}(v)} f(e)$  is called an **active node**.

## Preflows

### Definition:

A **labelling** is a function  $\ell: V \rightarrow \mathbb{N}$ . It is **valid** for preflow  $f$  if

- ▶  $\ell(u) \leq \ell(v) + 1$  for all edges in the residual graph  $G_f$  (only non-zero capacity edges!!!)
- ▶  $\ell(s) = n$
- ▶  $\ell(t) = 0$

### Intuition:

The labelling can be viewed as a height function. Whenever the height from node  $u$  to node  $v$  decreases by more than 1 (i.e., it goes very steep downhill from  $u$  to  $v$ ), the corresponding edge must be saturated.

## Preflows

## Preflows

### Lemma 3

A *preflow* that has a valid labelling saturates a cut.

#### Proof:

- ▶ There are  $n$  nodes but  $n + 1$  different labels from  $0, \dots, n$ .
- ▶ There must exist a label  $d \in \{0, \dots, n\}$  such that none of the nodes carries this label.
- ▶ Let  $A = \{v \in V \mid \ell(v) > d\}$  and  $B = \{v \in V \mid \ell(v) < d\}$ .
- ▶ We have  $s \in A$  and  $t \in B$  and there is no edge from  $A$  to  $B$  in the residual graph  $G_f$ ; this means that  $(A, B)$  is a saturated cut.

### Lemma 4

A *flow* that has a valid labelling is a maximum flow.

## Push Relabel Algorithms

#### Idea:

- ▶ start with some preflow and some valid labelling
- ▶ successively change the preflow while maintaining a valid labelling
- ▶ stop when you have a flow (i.e., no more active nodes)

Note that this is somewhat dual to an augmenting path algorithm. The former maintains the property that it has a feasible flow. It successively changes this flow until it saturates some cut in which case we conclude that the flow is maximum. A preflow push algorithm maintains the property that it has a saturated cut. The preflow is changed iteratively until it fulfills conservation constraints in which case we can conclude that we have a maximum flow.

## Changing a Preflow

An arc  $(u, v)$  with  $c_f(u, v) > 0$  in the residual graph is *admissible* if  $\ell(u) = \ell(v) + 1$  (i.e., it goes downwards w.r.t. labelling  $\ell$ ).

#### The push operation

Consider an active node  $u$  with *excess flow*

$f(u) = \sum_{e \in \text{into}(u)} f(e) - \sum_{e \in \text{out}(u)} f(e)$  and suppose  $e = (u, v)$  is an admissible arc with residual capacity  $c_f(e)$ .

We can send flow  $\min\{c_f(e), f(u)\}$  along  $e$  and obtain a new preflow. The old labelling is still valid (!!!).

- ▶ **saturating push:**  $\min\{f(u), c_f(e)\} = c_f(e)$   
the arc  $e$  is deleted from the residual graph
- ▶ **non-saturating push:**  $\min\{f(u), c_f(e)\} = f(u)$   
the node  $u$  becomes inactive

## Push Relabel Algorithms

#### The relabel operation

Consider an active node  $u$  that does not have an outgoing admissible arc.

Increasing the label of  $u$  by 1 results in a valid labelling.

- ▶ Edges  $(w, u)$  incoming to  $u$  still fulfill their constraint  $\ell(w) \leq \ell(u) + 1$ .
- ▶ An outgoing edge  $(u, w)$  had  $\ell(u) < \ell(w) + 1$  before since it was not admissible. Now:  $\ell(u) \leq \ell(w) + 1$ .

## Push Relabel Algorithms

### Intuition:

We want to send flow downwards, since the source has a height/label of  $n$  and the target a height/label of  $0$ . If we see an active node  $u$  with an admissible arc we push the flow at  $u$  towards the other end-point that has a lower height/label. If we do not have an admissible arc but excess flow into  $u$  it should roughly mean that the level/height/label of  $u$  should rise. (If we consider the flow to be water than this would be natural).

Note that the above intuition is very incorrect as the labels are integral, i.e., they cannot really be seen as the height of a node.

## Reminder

- ▶ In a **preflow** nodes may not fulfill conservation constraints; a node may have more incoming flow than outgoing flow.
- ▶ Such a node is called **active**.
- ▶ A labelling is **valid** if for every edge  $(u, v)$  in the residual graph  $\ell(u) \leq \ell(v) + 1$ .
- ▶ An arc  $(u, v)$  in residual graph is **admissible** if  $\ell(u) = \ell(v) + 1$ .
- ▶ A **saturation push** along  $e$  pushes an amount of  $c(e)$  flow along the edge, thereby saturating the edge (and making it disappear from the residual graph).
- ▶ A **non-saturating push** along  $e = (u, v)$  pushes a flow of  $f(u)$ , where  $f(u)$  is the **excess flow** of  $u$ . This makes  $u$  inactive.

## Push Relabel Algorithms

### Algorithm 48 $\text{maxflow}(G, s, t, c)$

```
1: find initial preflow  $f$ 
2: while there is active node  $u$  do
3:   if there is admiss. arc  $e$  out of  $u$  then
4:      $\text{push}(G, e, f, c)$ 
5:   else
6:      $\text{relabel}(u)$ 
7: return  $f$ 
```

In the following example we always stick to the same active node  $u$  until it becomes inactive but this is not required.

## Preflow Push Algorithm

Animation for push re-label algorithms is only available in the lecture version of the slides.

## Analysis

### Lemma 5

An active node has a path to  $s$  in the residual graph.

#### Proof.

- ▶ Let  $A$  denote the set of nodes that can reach  $s$ , and let  $B$  denote the remaining nodes. Note that  $s \in A$ .
- ▶ In the following we show that a node  $b \in B$  has excess flow  $f(b) = 0$  which gives the lemma.
- ▶ In the residual graph there are no edges into  $A$ , and, hence, no edges leaving  $A$ /entering  $B$  can carry any flow.
- ▶ Let  $f(B) = \sum_{v \in B} f(v)$  be the excess flow of all nodes in  $B$ .

Let  $f : E \rightarrow \mathbb{R}_0^+$  be a preflow. We introduce the notation

$$f(x, y) = \begin{cases} 0 & (x, y) \notin E \\ f((x, y)) & (x, y) \in E \end{cases}$$

We have

$$\begin{aligned} f(B) &= \sum_{b \in B} f(b) \\ &= \sum_{b \in B} \left( \sum_{v \in V} f(v, b) - \sum_{v \in V} f(b, v) \right) \\ &= \sum_{b \in B} \left( \sum_{v \in A} f(v, b) + \sum_{v \in B} f(v, b) - \sum_{v \in A} f(b, v) - \sum_{v \in B} f(b, v) \right) \\ &= - \sum_{b \in B} \sum_{v \in A} f(b, v) \\ &\leq 0 \end{aligned}$$

Hence, the excess flow  $f(b)$  must be 0 for every node  $b \in B$ .

## Analysis

### Lemma 6

The label of a node cannot become larger than  $2n - 1$ .

#### Proof.

- ▶ When increasing the label at a node  $u$  there exists a path from  $u$  to  $s$  of length at most  $n - 1$ . Along each edge of the path the height/label can at most drop by 1, and the label of the source is  $n$ .

### Lemma 7

There are only  $\mathcal{O}(n^2)$  relabel operations.

## Analysis

### Lemma 8

The number of *saturating pushes* performed is at most  $\mathcal{O}(mn)$ .

#### Proof.

- ▶ Suppose that we just made a saturating push along  $(u, v)$ .
- ▶ Hence, the edge  $(u, v)$  is deleted from the residual graph.
- ▶ For the edge to appear again, a push from  $v$  to  $u$  is required.
- ▶ Currently,  $\ell(u) = \ell(v) + 1$ , as we only make pushes along admissible edges.
- ▶ For a push from  $v$  to  $u$  the edge  $(v, u)$  must become admissible. The label of  $v$  must increase by at least 2.
- ▶ Since the label of  $v$  is at most  $2n - 1$ , there are at most  $n$  pushes along  $(u, v)$ .

### Lemma 9

The number of *non-saturating pushes* performed is at most  $\mathcal{O}(n^2m)$ .

#### Proof.

- ▶ Define a potential function  $\Phi(f) = \sum_{\text{active nodes } v} \ell(v)$
- ▶ A saturating push increases  $\Phi$  by  $\leq 2n$  (when the target node becomes active it may contribute at most  $2n$  to the sum).
- ▶ A relabel increases  $\Phi$  by at most  $1$ .
- ▶ A non-saturating push decreases  $\Phi$  by at least  $1$  as the node that is pushed from becomes inactive and has a label that is strictly larger than the target.
- ▶ Hence,  
$$\# \text{non-saturating\_pushes} \leq \# \text{relabels} + 2n \cdot \# \text{saturating\_pushes} \leq \mathcal{O}(n^2m) .$$

## Analysis

### Theorem 10

There is an implementation of the generic push relabel algorithm with running time  $\mathcal{O}(n^2m)$ .

## Analysis

#### Proof:

For every node maintain a list of admissible edges starting at that node. Further maintain a list of active nodes.

A push along an edge  $(u, v)$  can be performed in constant time

- ▶ check whether edge  $(v, u)$  needs to be added to  $G_f$
- ▶ check whether  $(u, v)$  needs to be deleted (saturating push)
- ▶ check whether  $u$  becomes inactive and has to be deleted from the set of active nodes

A relabel at a node  $u$  can be performed in time  $\mathcal{O}(n)$

- ▶ check for all outgoing edges if they become admissible
- ▶ check for all incoming edges if they become non-admissible

## Analysis

For special variants of push relabel algorithms we organize the neighbours of a node into a linked list (possible neighbours in the residual graph  $G_f$ ). Then we use the discharge-operation:

#### Algorithm 49 discharge( $u$ )

```
1: while  $u$  is active do
2:    $v \leftarrow u.\text{current-neighbour}$ 
3:   if  $v = \text{null}$  then
4:     relabel( $u$ )
5:      $u.\text{current-neighbour} \leftarrow u.\text{neighbour-list-head}$ 
6:   else
7:     if  $(u, v)$  admissible then push( $u, v$ )
8:     else  $u.\text{current-neighbour} \leftarrow v.\text{next-in-list}$ 
```

Note that  $u.\text{current-neighbour}$  is a global variable. It is only changed within the discharge routine, but keeps its value between consecutive calls to discharge.

### Lemma 11

If  $v = \text{null}$  in Line 3, then there is no outgoing admissible edge from  $u$ .

#### Proof.

- ▶ While pushing from  $u$  the current-neighbour pointer is only advanced if the current edge is not admissible.
- ▶ The only thing that could make the edge admissible again would be a relabel at  $u$ .
- ▶ If we reach the end of the list ( $v = \text{null}$ ) all edges are not admissible.  $\square$

This shows that  $\text{discharge}(u)$  is correct, and that we can perform a relabel in Line 4.

In order for  $e$  to become admissible the other end-point say  $v$  has to push flow to  $u$  (so that the edge  $(u, v)$  re-appears in the residual graph). For this the label of  $v$  needs to be larger than the label of  $u$ . Then in order to make  $(u, v)$  admissible the label of  $u$  has to increase.
