

## Technique 1: Round the LP solution.

We first solve the LP-relaxation and then we round the fractional values so that we obtain an integral solution.

**Set Cover relaxation:**

$$\begin{array}{ll} \min & \sum_{i=1}^k w_i x_i \\ \text{s.t.} & \forall u \in U \quad \sum_{i:u \in S_i} x_i \geq 1 \\ & \forall i \in \{1, \dots, k\} \quad x_i \in [0, 1] \end{array}$$

Let  $f_u$  be the number of sets that the element  $u$  is contained in (the frequency of  $u$ ). Let  $f = \max_u \{f_u\}$  be the maximum frequency.

## Technique 1: Round the LP solution.

### Rounding Algorithm:

Set all  $x_i$ -values with  $x_i \geq \frac{1}{f}$  to 1. Set all other  $x_i$ -values to 0.

# Technique 1: Round the LP solution.

## Lemma 2

*The rounding algorithm gives an  $f$ -approximation.*

**Proof:** Every  $u \in U$  is covered.

- ▶ We know that  $\sum_{i:u \in S_i} x_i \geq 1$ .
- ▶ The sum contains at most  $f_u \leq f$  elements.
- ▶ Therefore one of the sets that contain  $u$  must have  $x_i \geq 1/f$ .
- ▶ This set will be selected. Hence,  $u$  is covered.

## Technique 1: Round the LP solution.

The cost of the rounded solution is at most  $f \cdot \text{OPT}$ .

$$\begin{aligned}\sum_{i \in I} w_i &\leq \sum_{i=1}^k w_i (f \cdot x_i) \\ &= f \cdot \text{cost}(x) \\ &\leq f \cdot \text{OPT} .\end{aligned}$$

## Technique 2: Rounding the Dual Solution.

### Relaxation for Set Cover

**Primal:**

$$\begin{array}{ll} \min & \sum_{i \in I} w_i x_i \\ \text{s.t. } \forall u & \sum_{i: u \in S_i} x_i \geq 1 \\ & x_i \geq 0 \end{array}$$

**Dual:**

$$\begin{array}{ll} \max & \sum_{u \in U} y_u \\ \text{s.t. } \forall i & \sum_{u: u \in S_i} y_u \leq w_i \\ & y_u \geq 0 \end{array}$$

## Technique 2: Rounding the Dual Solution.

### Rounding Algorithm:

Let  $I$  denote the index set of sets for which the dual constraint is tight. This means for all  $i \in I$

$$\sum_{u:u \in S_i} y_u = w_i$$

## Technique 2: Rounding the Dual Solution.

### Lemma 3

*The resulting index set is an  $f$ -approximation.*

#### **Proof:**

Every  $u \in U$  is covered.

- ▶ Suppose there is a  $u$  that is not covered.
- ▶ This means  $\sum_{u:u \in S_i} y_u < w_i$  for all sets  $S_i$  that contain  $u$ .
- ▶ But then  $y_u$  could be increased in the dual solution without violating any constraint. This is a contradiction to the fact that the dual solution is optimal.

## Technique 2: Rounding the Dual Solution.

**Proof:**

$$\begin{aligned}\sum_{i \in I} w_i &= \sum_{i \in I} \sum_{u: u \in S_i} y_u \\ &= \sum_u |\{i \in I : u \in S_i\}| \cdot y_u \\ &\leq \sum_u f_u y_u \\ &\leq f \sum_u y_u \\ &\leq f \text{cost}(x^*) \\ &\leq f \cdot \text{OPT}\end{aligned}$$

Let  $I$  denote the solution obtained by the first rounding algorithm and  $I'$  be the solution returned by the second algorithm. Then

$$I \subseteq I' .$$

This means  $I'$  is never better than  $I$ .

- ▶ Suppose that we take  $S_i$  in the first algorithm. I.e.,  $i \in I$ .
- ▶ This means  $x_i \geq \frac{1}{f}$ .
- ▶ Because of **Complementary Slackness Conditions** the corresponding constraint in the dual must be tight.
- ▶ Hence, the second algorithm will also choose  $S_i$ .

## Technique 3: The Primal Dual Method

The previous two rounding algorithms have the disadvantage that it is necessary to solve the LP. The following method also gives an  $f$ -approximation without solving the LP.

For estimating the cost of the solution we only required two properties.

1. The solution is dual feasible and, hence,

$$\sum_u y_u \leq \text{cost}(x^*) \leq \text{OPT}$$

where  $x^*$  is an optimum solution to the primal LP.

2. The set  $I$  contains only sets for which the dual inequality is tight.

Of course, we also need that  $I$  is a cover.

## Technique 3: The Primal Dual Method

### Algorithm 1 PrimalDual

- 1:  $y \leftarrow 0$
- 2:  $I \leftarrow \emptyset$
- 3: **while** exists  $u \notin \bigcup_{i \in I} S_i$  **do**
- 4:     increase dual variable  $y_u$  until constraint for some  
      new set  $S_\ell$  becomes tight
- 5:      $I \leftarrow I \cup \{\ell\}$

## Technique 4: The Greedy Algorithm

### Algorithm 1 Greedy

- 1:  $I \leftarrow \emptyset$
- 2:  $\hat{S}_j \leftarrow S_j$  for all  $j$
- 3: **while**  $I$  not a set cover **do**
- 4:      $\ell \leftarrow \arg \min_{j: \hat{S}_j \neq \emptyset} \frac{w_j}{|\hat{S}_j|}$
- 5:      $I \leftarrow I \cup \{\ell\}$
- 6:      $\hat{S}_j \leftarrow \hat{S}_j - S_\ell$  for all  $j$

In every round the Greedy algorithm takes the set that covers remaining elements in the most **cost-effective** way.

We choose a set such that the ratio between cost and still uncovered elements in the set is minimized.

## Technique 4: The Greedy Algorithm

### Lemma 4

Given positive numbers  $a_1, \dots, a_k$  and  $b_1, \dots, b_k$ , and  $S \subseteq \{1, \dots, k\}$  then

$$\min_i \frac{a_i}{b_i} \leq \frac{\sum_{i \in S} a_i}{\sum_{i \in S} b_i} \leq \max_i \frac{a_i}{b_i}$$

## Technique 4: The Greedy Algorithm

Let  $n_\ell$  denote the number of elements that remain at the beginning of iteration  $\ell$ .  $n_1 = n = |U|$  and  $n_{s+1} = 0$  if we need  $s$  iterations.

In the  $\ell$ -th iteration

$$\min_j \frac{w_j}{|\hat{S}_j|} \leq \frac{\sum_{j \in \text{OPT}} w_j}{\sum_{j \in \text{OPT}} |\hat{S}_j|} = \frac{\text{OPT}}{\sum_{j \in \text{OPT}} |\hat{S}_j|} \leq \frac{\text{OPT}}{n_\ell}$$

since an optimal algorithm can cover the remaining  $n_\ell$  elements with cost  $\text{OPT}$ .

Let  $\hat{S}_j$  be a subset that minimizes this ratio. Hence,  
 $w_j / |\hat{S}_j| \leq \frac{\text{OPT}}{n_\ell}$ .

## Technique 4: The Greedy Algorithm

Adding this set to our solution means  $n_{\ell+1} = n_{\ell} - |\hat{S}_j|$ .

$$w_j \leq \frac{|\hat{S}_j| \text{OPT}}{n_{\ell}} = \frac{n_{\ell} - n_{\ell+1}}{n_{\ell}} \cdot \text{OPT}$$

## Technique 4: The Greedy Algorithm

$$\begin{aligned}\sum_{j \in I} w_j &\leq \sum_{\ell=1}^s \frac{n_\ell - n_{\ell+1}}{n_\ell} \cdot \text{OPT} \\ &\leq \text{OPT} \sum_{\ell=1}^s \left( \frac{1}{n_\ell} + \frac{1}{n_\ell - 1} + \dots + \frac{1}{n_{\ell+1} + 1} \right) \\ &= \text{OPT} \sum_{i=1}^k \frac{1}{i} \\ &= H_n \cdot \text{OPT} \leq \text{OPT}(\ln n + 1) .\end{aligned}$$

## Technique 4: The Greedy Algorithm

A tight example:

## Technique 5: Randomized Rounding

One round of randomized rounding:

Pick set  $S_j$  uniformly at random with probability  $1 - x_j$  (for all  $j$ ).

**Version A:** Repeat rounds until you have a cover.

**Version B:** Repeat for  $s$  rounds. If you have a cover STOP.  
Otherwise, repeat the whole algorithm.

**Probability that  $u \in U$  is not covered (in one round):**

$$\begin{aligned}\Pr[u \text{ not covered in one round}] &= \prod_{j:u \in S_j} (1 - x_j) \leq \prod_{j:u \in S_j} e^{-x_j} \\ &= e^{-\sum_{j:u \in S_j} x_j} \leq e^{-1} .\end{aligned}$$

**Probability that  $u \in U$  is not covered (after  $\ell$  rounds):**

$$\Pr[u \text{ not covered after } \ell \text{ round}] \leq \frac{1}{e^\ell} .$$

$$\begin{aligned} & \Pr[\exists u \in U \text{ not covered after } \ell \text{ round}] \\ &= \Pr[u_1 \text{ not covered} \vee u_2 \text{ not covered} \vee \dots \vee u_n \text{ not covered}] \\ &\leq \sum_i \Pr[u_i \text{ not covered after } \ell \text{ rounds}] \leq ne^{-\ell} . \end{aligned}$$

## Lemma 5

*With high probability  $\mathcal{O}(\log n)$  rounds suffice.*

**With high probability:**

For any constant  $\alpha$  the number of rounds is at most  $\mathcal{O}(\log n)$  with probability at least  $1 - n^{-\alpha}$ .

**Proof:** We have

$$\Pr[\text{\#rounds} \geq (\alpha + 1) \ln n] \leq n e^{-(\alpha+1) \ln n} = n^{-\alpha} .$$

# Expected Cost

- ▶ Version A.

Repeat for  $s = (\alpha + 1) \ln n$  rounds. If you don't have a cover simply take for each element  $u$  the cheapest set that contains  $u$ .

$$E[\text{cost}] \leq (\alpha + 1) \ln n \cdot \text{cost}(LP) + (n \cdot \text{OPT}) n^{-\alpha} = \mathcal{O}(\ln n) \cdot \text{OPT}$$

## Expected Cost

► Version B.

Repeat for  $s = (\alpha + 1) \ln n$  rounds. If you don't have a cover simply repeat the whole process.

$$E[\text{cost}] = \Pr[\text{success}] \cdot E[\text{cost} \mid \text{success}] \\ + \Pr[\text{no success}] \cdot E[\text{cost} \mid \text{no success}]$$

This means

$$E[\text{cost} \mid \text{success}] \\ = \frac{1}{\Pr[\text{succ.}]} \left( E[\text{cost}] - \Pr[\text{no success}] \cdot E[\text{cost} \mid \text{no success}] \right) \\ \leq \frac{1}{\Pr[\text{succ.}]} E[\text{cost}] \leq \frac{1}{1 - n^{-\alpha}} (\alpha + 1) \ln n \cdot \text{cost}(\text{LP}) \\ \leq 2(\alpha + 1) \ln n \cdot \text{OPT}$$

for  $n \geq 2$  and  $\alpha \geq 1$ .

Randomized rounding gives an  $\mathcal{O}(\log n)$  approximation. The running time is polynomial with high probability.

### Theorem 6 (without proof)

*There is no approximation algorithm for set cover with approximation guarantee better than  $\frac{1}{2} \log n$  unless NP has quasi-polynomial time algorithms (algorithms with running time  $2^{\text{poly}(\log n)}$ ).*

# Integrality Gap

The **integrality gap** of the SetCover LP is  $\Omega(\log n)$ .

- ▶  $n = 2^k - 1$
- ▶ Elements are all vectors  $\vec{x}$  over  $GF[2]$  of length  $k$  (excluding zero vector).
- ▶ Every vector  $\vec{y}$  defines a set as follows

$$S_{\vec{y}} := \{\vec{x} \mid \vec{x}^T \vec{y} = 1\}$$

- ▶ each set contains  $2^{k-1}$  vectors; each vector is contained in  $2^{k-1}$  sets
- ▶  $x_i = \frac{1}{2^{k-1}} = \frac{2}{n+1}$  is fractional solution.

# Integrality Gap

Every collection of  $p < k$  sets does not cover all elements.

Hence, we get a gap of  $\Omega(\log n)$ .
